If you have not done so go to the speed controller main page for flow chart identification. Testing of the EZGO ELECTRONIC SPEED CONTROL SERIES Drive system. With the resistor in place the reading should be 0.1 to 3 volts less than battery voltage. If the reading is more than 3 volts less the battery voltage, the resistor is faulty. If the voltage is the same as the battery voltage with the resistor disconnected the solenoid contacts are welded, replace the solenoid. Solenoid test is done with the resistor removed from one large terminal. If no, the solenoid has failed. This circuit consists of a series of switches and is easily traced using the solenoid activation circuit diagrams available on the forum. When I say check to see that positive and negative exist at the small terminals. I mean that there should be 36 V positive at the small terminal with yellow wire when you press the gas pedal with the key on and cart in gear. This can be checked with your voltmeter by putting the black test lead on the battery pack main negative and the red test lead on the small posts with the yellow wire. And I mean that there should be 36 V negative at the small terminal with the blue or black wire at the same time. This can be checked with your voltmeter by putting the black test lead on the battery main positive in the red test lead on the small posts with the blue or black wire. <http://oumkua.com/userfiles/canon-dw-100-dvd-burner-manual.xml>

- **1.0.**

This can Also be tested by putting a test lead on each small terminal and pressing the gas pedal. The meter should read 36 V when the gas is pressed. If this voltage does exist when the gas pedal is pressed then the solenoid should click and engage. If this voltage does not exist when the pedal is pressed then you have a problem in the solenoid activation circuit. This circuit begins at a battery source go through the key switch the foot pedal switch and culminates at the solenoid. I hope this helps ITS INDUCTIVE THROTTLE SENSOR There are three parts to the system. 1. a voltage source from the controller 2. a plunger and coil in the pedal box under the floor mat 3. a throttle position translator in the controller. Basically, when you press down on the pedal, a metal rod is inserted into the sensor coil in the pedal box, changing the inductance of the coil, which reduces the voltage signal sent through it. This varying voltage signal tells the controller how much current the driver wants passed to the motor. Got it Good. Since the controller provides this signal different controls will show different voltages. And there are different values for different drive systems with the Curtis control. With meter neg. probe on the B terminal, use the positive lead to probe the white wire in the controller main molex connector. With pedal on floor, it should give the high end reading shown above. These readings are true for the Curtis control. The Alltrax control uses a higher voltage. The throttle signal should start at 10 V and go down to 6 V. If the signal is out of range the controller will not work and the ITS sensor must be replaced. CHECKING CONTROLLER INPUT Connect probe to B terminal. The reading should indicate approx. 0 volts with the resistor REMOVED and the pedal not pressed in the last 1530 minutes. CHECKING CONTROLLER OUTPUT Slowly depress accelerator pedal until the solenoid engages. Watch the voltmeter. The reading should show the battery pack

voltage. <http://www.cukiernia-waltar.pl/qcms/userfiles/canon-dw-100-manual.xml>

Now slowly depress the pedal and watch the reading, it should go down to nearly 0 volts. If the voltage starts at full pack and goes down near zero when the pedal is depressed and the motor is not responding then the problem lies in the high amperage side of the drive circuit. Check the cable connections, the forward and reverse switch, and the motor. The voltage should go from Zero when solenoid clicks to full pack voltage when pedal is on floor. Be certain that the battery pack voltage is not dropping dramatically when you try to go this may indicate one or more bad batteries which may prohibit the cart from running. Some cable may be ready to come off. Four contacts are stationary in the switch housing. And four contacts are on a rotating center cam. This configuration allows for three configurations; forward, neutral, and reverse. Contact is maintained by spring tension and friction. You can test for continuity between parallel pairs of stationary lugs in forward and reverse position. However, the test will not guarantee that the contact is good enough to withstand high amperage. It is possible to have a positive continuity test that will not hold up to actual use. A visual inspection is best. If all of the four studs are not identical in color, one or more may have gotten hot. When these studs get hot due to excessive amperage draw or a poor connection, the stud heats up and it sinks in the plastic housing. This compromises the contact with the lug in the rotating cam. If a stud has sunk or changed angle so it appears to lean then the complete switch must be replaced. A simple voltage check will verify operation. MOTOR UNWANTED CONTINUITY TEST The following tests can assist in troubleshooting. Disconnect all wires to the motor and label them Make sure none of the terminals are grounded to the motor or cart With your meters set on JACK UP REAR WHEELS or otherwise secure the rear end up off of the ground. Connect probe of meter on Battery Pack Negative post.

The same voltage should be present. If not, inspect all solenoid and battery cables. Perform a continuity test on wires 1 and 2, 3 and 4 TO THE CONTROLLER Turn the key switch ON and place the gear selector in Forward. The reading should be 0.1 to 3 volts less than battery voltage. If the voltage is the same as the battery voltage, replace the solenoid. The reading should be slightly above 14 volts but LESS than 16 volts. If the voltage is below 14 volts, the Throttle Sensor MAY be faulty. Above 16 volts, the controller MAY be faulty. Separate the 6 six pin connector only 4 are used between the pedal box and the controller. If the voltage goes to 1416 volts, the sensor is faulty. If the voltage remains below 14 or above 16 volts, the controller is faulty. RECONNECT the 6 six pin connector. Depress the pedal slowly. The reading should be 0.45 0.53 volts just as the microswitch is activated. Depress the pedal slowly to full throttle. The reading should move smoothly to about 1.5 volts. If the reading is incorrect, The Throttle Sensor is defective. Disconnect all wires to the motor and label them Make sure none of the terminals are grounded to the motor or cart F1 terminal to motor frame You should have continuity present between F1 and F2 and A1 and A2 but NOT BETWEEN ANY A and ANY F Terminal. If any of these test fail, the motor will not operate correctly. I hope this information has helped. I regret there is not enough time in a day for me to personally walk everybody through their cart diagnostics. If you need assistance please post on buggiesgonewild.com I will look for your posts there. They open and close mechanically. You can test function with a voltmeter if you first verify 36v in on the supply side of the switch, then mechanically trigger the switch, and test for 36v on the output side. With the multimeter set to continuity or ohms you can disconnect both sides of the switch and connect it to the meter. The meter will show the connection making and breaking.

<https://skazkina.com/ru/3rd-1999-edition-sadc-road-traffic-signs-manual>

If not check meter settings and test a different switch. Once you are certain your test method is correct retest the switch in question. The solenoid should be engaged anytime the pedal is depress, whether that is a small amount or pushed to the floor. CAUTION. Anytime you are testing a no go cart it must be up off the floor in the rear because it may start unexpectedly while testing which may

cause body and property damage. SO when positioning the pedal for testing you have to ask yourself If it does start unexpectedly do I want a slow start or a full speed start. If you are using a brick to hold the pedal down for testing put an appropriate amount of wood or. If your cart starts showing these symptoms, the first thing you should look at is your speed controller. You will likely find the switch under the seat of your golf car,t but if you're having trouble finding it, consult your owner's manual. Once disconnected, you should remove the speed controller cover and then reconnect the negative cable. Sometimes the problem can be as simple as some loose wiring and all you need to do is make sure everything is plugged in tight. Lastly, you can check the voltage of the controller battery by connecting both the positive and negative probes to the battery. If there is an issue with your cart's solenoid, some of the symptoms can be the same as a malfunctioning speed controller. Attach the positive probe to the solenoid post nearest the battery and get the reading. If the solenoid and battery readings are identical, there is an issue with the solenoid. However, if the reading isn't at least 3 volts less than the battery, the problem is with the resistor and it should be replaced. The two possible problems you can identify this way is either a bad speed controller, or a bad directional switch or motor. If you do, we hope you can use the steps in this article to help you identify and fix the issue. Mt Pleasant, SC 29464 843 8818894. At the beginning of each major section is a list of tools that will be required to perform the operations desired in that section. Before working on the engine, read and understand the text and in particular each NOTE, CAUTION and WARNING. Some illustrations may show components that differ from your engine. This is the result of ongoing improvements to the engine design. This will help prevent accidents and reduce the possibility of mistakes that could damage or impair the performance of the engine. Crankshaft and balancer shaft bearings should be cleaned and inspected; and removed only if they appear to be damaged or excessively worn. Remove bearings that are pitted, nicked, burred, discolored or that rotate roughly or noisily.

Because some mating parts with wear surfaces were machined together when the engine was manufactured, or have established wear patters during operation, the reassembly of engine parts in their original positions and orientations, with their original mating parts, is critical to the performance and life expectancy of the engine. Mark and sort all parts as they are disassembled so that they will be reassembled and installed in their original positions. Remove the Air Cleaner A variety of air cleaner configurations exist. Remove the Blower Housing See Fig. A1 "Engine" on page A4 A. Using a 10mm socket, remove the three 3 remaining bolts ITEM 7 and remove the blower housing ITEM 6 from the engine. Later models have four 4 bolts and no stud F.

Remove the cam pulley retaining bolt ITEM 16 and the cam pulley ITEM 24. B. Using a 10mm socket, loosen the four 4 rocker arm nuts ITEM 7. 1. Remove the pulley alignment key. Using a nonferrous nonsteel punch, drive the back end of the key down into the keyway, which will push the front end up. C. With a medium flat blade screwdriver, turn the four 4 rocker adjustment screws ITEM 8 counterclockwise until they no longer exert any force on the camshaft ITEM 9 and it can rotate freely. 2. With the punch, gently drive the upraised key out of the keyway. D. Remove the rocker assembly. Remove the Rear Timing Belt Cover See Fig. A1 "Engine" on page A4 A. Using a 10mm socket, remove the two 2 bolts ITEM 26 that attach the rear timing belt cover ITEM 25 to the engine. Remove the Front Cylinder Baffle See Fig. A1 "Engine" on page A4 A. Using a 10mm socket, remove the two 2 bolts ITEM 28 that attach the baffle ITEM 27 to the engine. Remove the Valve Cover and Gasket See Fig. A2 "Cylinder Head Components" on page A5 A. Using a 10mm socket, remove the six 6 bolts ITEM 3 that attach the rocker cover ITEM 1 to the cylinder head. Remove the rocker cover and gasket ITEM 2. Remove the Rocker Assembly and Camshaft See Fig. A2 "Cylinder Head Components" on page A5 The rocker shafts in some early engines were manufactured with a threaded hole in the end, into which a blot is placed in order to pull the shaft from the cylinder head. Do not allow the camshaft lobes or bearing surfaces to scrape against the cylinder head. Because these parts have established wear patterns during operation, mark and sort them as they are disassembled so that they will be reassembled in their original positions. A. Remove the camshaft cover ITEM 4. Page A2 2. Using a rubber or wooden mallet, gently tap loose the protruding edge of the camshaft cover and pull it away from the engine. 1.
