Rebinyr [®] Demonstrates Superior Factor 9 Levels in Phase 1 Study, Showing Promising Results for Hemophilia B Treatment Rebinyr is a prescription medication given as an infusion into the vein to treat hemophilia B. It's essential to follow the recommended dosage and consult with your healthcare provider before taking Rebinyr or any other medications. Common side effects of Rebinyr include reactions at the infusion site, such as bruising, bleeding, swelling, pain, or redness, as well as itching and rash. In rare cases, your body may produce inhibitors against Factor IX, which can affect how Rebinyr works. Regular blood tests may be necessary to monitor for these inhibitors. In severe allergic reactions, such as hives, chest tightness, wheezing, difficulty breathing, or facial swelling, seek immediate medical attention. Additionally, if you experience chest pain, leg tenderness, or swelling, notify your healthcare provider right away. Animal studies have raised concerns about Polyethylene Glycol (PEG) accumulation in certain brain cells, but its implications for humans are unclear. It's crucial to discuss any potential side effects with your healthcare provider and report them to the FDA via their MedWatch program.
